NATIONAL POPULATION PROJECTION

2007-2022

July 2009

PREFACE

The National Institute of Statistics of Rwanda (NISR) is pleased to present in this bulletin the update of National Population Projection for the period 2007-2022. Population projection is generally carried out after the release of population census results. However, projection updating is necessary whenever reality, concerning factors of population growth, shows different levels from the assumptions on which the initial projection was based. In this regard, the Interim Demographic and Health Survey of 2007/2008 provide fertility estimates which deviate from the previously assumed values that have been incorporated in the initial exercise of population projection. This in fact has made the development of a new set of population projections a necessity.

Population projections are of substantial importance at national, sub-national and sectoral levels. Planning and programming for developmental policies and strategies may imply misuse of resources if not based on scientifically driven population projections and estimates. For this reason, we call upon all potential users to rely upon these estimated population figures (especially the Median Variant) in their planning activities.

This exercise would have not been successful without the dedication and hard work of the relevant staff of Social and Demographic Statistics Unit headed by RUTERANA Baudouin Abdon, and the invaluable contributions of Dr. Mohamed Aboulata and of Mr. Messan Pierre advisors of NISR deserve my greatest appreciation and gratitude.

MURANGWA Yusuf
Acting Director General of National
Institute of Statistics of Rwanda (NISR)

CHAPTER 1: METHODOLOGY

I.1 BACKGROUND

Population Projections are usually carried out immediately after the release of census results so as to provide annual estimates of future population counts broken down by age and sex. Nonetheless, Projections are to be updated whenever new evidences concerning factors of population growth emerge, especially when such evidences are different from the assumptions on which the projection was based. In this context, the 2007/2008 Rwanda Interim Demographic and Health Survey (RIDHS) has shown different fertility and mortality levels than those incorporated in the latest (2004) set of Population Projections which was carried out after the release of the 2002 Census results. This is in fact what has prompted updating the population projections of Rwanda.

On the basis of the resulting population projections, sectoral projections will be carried out for dual reasons: first, to assess the impact of different scenarios of population growth on Health, Education, Economic, Urbanization, and Agricultural sectors, second to provide forecasts on several planning elements that may help concerned organizations. This will be published in separate bulletin.

Needless to say that population and sectoral projections are instrumental for the purposes of national and sectoral planning processes, which can go astray if not founded on reliable population estimates.

I. 2- METHODOLOGY OF POPULATION PROJECTION

The national projections require measuring fertility, mortality and international migration in the base projection year, as well as projecting the future trend of those factors of population growth. Three projection variants have been made based on three different fertility trends (low, median and high). The same mortality projection was used in the three projection variants. The 2002 census population has been retained as the projection base year population, yet it was evaluated for coverage and age reporting errors, where necessary adjustments were introduced. The Projection Period was determined to be 2002-2022. National and Sectoral projections were carried out using respectively DEMPROJ and RAPID modules of SPECTRUM Software.

The following subsections provide descriptions of the procedures followed to handle base year population; projection of fertility and mortality; and migration.

I.2.1 Base Year Population

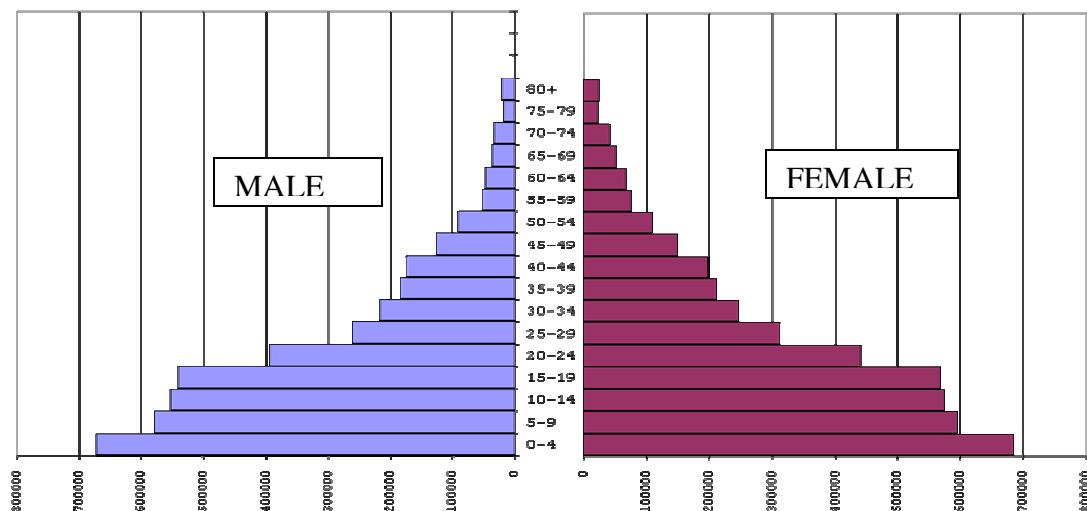

The age/sex structure of the 2002 Population Census has been evaluated for coverage and age reporting. With regard to coverage, the Post Enumeration Survey conducted

after the completion of the field work of the 2002 Census indicates that the net under-coverage rate amounts to 2.9%. Thus the census population has to be adjusted upward to account for that level of net under-enumeration. In doing so, under-enumeration is assumed invariant with age and sex. In other words, the observed census age-sex structure was kept unchanged after adjusting for under-enumeration

Age reporting has been investigated from different angles: first, a population pyramid was constructed and analyzed; second, age-specific sex ratios were investigated; third, age ratio analysis was performed; and finally the United Nations Age-Sex accuracy index was measured.

a- The Population Pyramid: In order to check consistency of age reporting based on five-year age grouping of the population of both sexes, the Population Pyramid was drawn. Graph 1 shows the population pyramid of the 2002 Census. With a broad base and a gradual tapering off as age moves up, the Pyramid is typical for a young population age structure characterized by high fertility and mortality. Nonetheless, the sharp decline in the age groups 20-24 and 25-29 for both sexes relative to preceding and subsequent age groups deserves further investigation before arriving at a conclusion that such irregularity in the age structure for both five-year age groups may be attributable to age misreporting in census data. The abnormal circumstances that Rwanda has gone through in the mid Nineties, accompanying the 1994 genocide, must have had noticeable impacts on the population age structures measured in the 2002 and even subsequent censuses to be carried out in the future. The population in the age groups 20-24 and 25-29 in 2002 were of ages 12-16 and 17-21 in 1994. Probably the populations of such age segments as well as older population were exposed to massive murder and/or emigration during the genocide period. One other factor that may have contributed to this irregularity is the effects of mortality decline occurred in recent years, i.e., from 1995 onward. Mortality decline manifests abnormally lower population numbers in older age groups (prior to mortality decline) compared with younger ones (experiencing lower mortality). The consistent pattern of males and females concerning this sharp decline of the population in both age groups lends further support to the proposition that it is likely to be real rather than age misreporting.

Graph 1: Population by Age and Sex

b- Sex-Ratio analysis: The second method for checking age reporting is the analysis of age-specific sex ratios. Surprisingly, lower sex ratio than normal is persistent in all ages especially in young and middle age groups. The extremely lower sex ratios at older ages are, to some what, justifiable due to higher male mortality at such ages. Three different patterns of sex ratio by age are observed: the first shows values in the nineties for younger age groups till ages 20-24; while the second is in the eighties for middle age groups till ages 50-54; the third pattern is either in the sixties or seventies for older ages (Table 3). The absence of tangible disturbances in the sex ratios from an age group to the following one, rules out the possibility of substantial sex differential in census under-coverage and/or age misreporting. Moreover, although it is an element of the UN Age-Sex Accuracy index (presented hence after), the sex ratio score (defined as the average absolute deviation of age-to-age differences in sex ratios) shows a very modest value (3.4) which is not very far away from the ideal situation of zero value.

Now, a question poses itself, why sex ratio of the whole population of Rwanda whether in its entirety (91.3%) or disaggregated by age is lower than the standard. Possibly higher male mortality in early childhood and adulthood coupled with past waves of male emigration in the middle age groups, are behind this phenomenon.

c- Age-Ratio analysis: The third approach for assessing age reporting is to carry out Age Ratio analysis for males and females for the purpose of measuring Age Accuracy Index. Age ratio is defined as the ratio of a population in a certain age group to one third of the sum of the population in the same age group and the population in the previous and following age groups, expressed as a percentage. On the basis of the assumption that the population in the three adjacent age groups change linearly over those ages, the deviation of the Age Ratio from 100 indicates age misreporting. The average of the absolute deviation of age ratios from 100, known as Age Accuracy Index, is taken as an overall measure of age misreporting errors. The lower the age accuracy index, the more adequate the census data on age would appear to be. Table 1 indicates that the Age Accuracy Index of the 2002 Census of Rwanda is 5.2 for males and 4.4 for females. These results suggest that reporting of age is satisfactory for both males and females, especially when we look in the experiences of other countries (see Table 3)

Table 1
Age Accuracy Index for Rwanda, 2002

Age Group	Male population	Female population	Male age ratio	Female age ratio	Deviation from 100 (male)	Deviation from 100 (female)
0-4	655090	665141	---	---	---	---

65-69	35178	49750	94.76	95.43	5.24	4.56
70-74	30970	40050	---	---	---	---
75+	34946	44672	---	---	---	---
Total(irrespective of sign)	3879448	4249105	----	---	68.42	57.80
Average	---	---	---	---	5.26	4.44

d- The United Nations age-sex accuracy index: In this index the mean of the differences from age- to- age in reported sex ratios, without regard to sign, is taken as a measure of accuracy of the observed sex ratios, as previously indicated. On the assumption that these age-to- age changes should approximate zero. The U.N. age-sex accuracy index combines the sum of (a) the mean deviation of the age ratios for males from 100, (b) the mean deviation of the age ratios for females from 100 and (c) three times the mean of the age- to- age differences in reported sex ratios. In the U.N. procedure, the age ratio is defined as the ratio of the population in a given age group to one-half the sum of the populations in the preceding and following groups. The calculation of the U.N. age-sex accuracy index of Rwanda, 2002 is illustrated in Table 2. Census age-sex data were described by the United Nations as “accurate”, “inaccurate”, or “highly inaccurate” depending on whether the U.N. index was under 20, 20-40, or over 40. Although the value of the U.N. index for Rwanda lies in the beginning of the second category (24.5), age reporting may be judged as acceptable in view of the expected real irregularities in the age distribution due to the civil war, genocide and migration that Rwanda has experienced in the Nineties. Furthermore, the comparison of the U.N. index of Rwanda with other countries lends further support to this conclusion (see Table 3).

In view of above evaluative analysis of age reporting of the 2002 census of Rwanda, it has been concluded that the age distributions of males and females are acceptable, so smoothing is not needed as it may conceal some irregularities which can be real. Nonetheless, adjustment was made to account for net under-enumeration, as previously noted. The age distributions were shifted from the census date (15 of August) to mid 2002.

Table 2
The U.N. Age-Sex Accuracy Index for Rwanda, 2002

Age Group	Male population	Female population	Male age ratio	Female age ratio	Deviation from 100 (male)	Deviation from 100 (female)	Sex ratio	Sex ratio difference

I.2.2 - Fertility Projection

Fertility is the most important factors of population growth influencing population projection. For this reason, alternative assumptions of future fertility are generally made. In the present situation, three assumptions are adopted: Intermediate, Low, and High. The intermediate assumption is merely an extrapolation of past fertility trend into the future, while High assumption hypnotizes constant fertility level and pattern in the future. The Low assumption presupposes the realization of a specific fertility target in the year 2020. The following subsections provide details of the three fertility assumptions.

I.2.2.1 Median fertility assumption

The Demographic and Health Survey (DHS) is the only reliable source for fertility estimates in Rwanda. Four rounds of DHS have been conducted in the country in the years 1992, 2000, 2005, and an Interim Survey in 2007. In all surveys fertility is measured for the three-year period preceding the field visits. Data on women birth history are used for estimating fertility. Table 4 exhibits Total Fertility Rates (TFR) and Age-Specific fertility Rates (ASFR) for the above mentioned surveys.

Table 4
Total Fertility Rates and Age Specific Fertility Rates
In the DHS Surveys of 1992, 2000, 2005 and 2007

Age group	DHS 1992		DHS 2000		DHS 2005		DHS 2007	
	ASFR	%	ASFR	%	ASFR	%	ASFR	%
15-19	60	4.8	52	4.5	42	3.4	40	3.6
20-24	227	18.2	240	20.6	235	19.4	211	19.1
25-29	294	23.6	272	23.3	305	25.1	272	24.7
30-34	270	21.7	257	22.0	273	22.5	246	22.3
35-39	214	17.2	190	16.3	211	17.4	209	19.0
40-44	135	10.8	123	10.5	117	9.6	105	9.5
45-49	46	3.7	33	2.8	32	2.6	20	1.8
Total	1246	100.0	1167	100.0	1215	100.0	1103	100.0
TFR	6.2	--	5.8	--	6.1	--	5.5	--

Source: DHS Survey reports

For the purpose of estimating future fertility, past fertility levels and patterns have been analyzed with the aim of fitting a model that can be used to estimate fertility in future time points. In other words, a linear or curvilinear model, whichever better fits the data and simulates the nature of the relationship between fertility measure as dependent variable and time as independent variable is to be sought. To this end, the following exponential model has been attempted to regress TFR on time:

$TFR=a \cdot \text{Exp}(bt)$; where ‘t’ denotes time in years, and ‘a’ and ‘b’ are constants to be estimated.

This exponential model is transferred into log linear model as:

$$\begin{aligned}\text{Ln}(TFR) &= \text{Ln}(a) + bt \\ &= a' + bt , \quad \text{where } a' = \text{Ln}(a)\end{aligned}$$

The rationale behind using the exponential model is that with declining fertility over time, the pace of fertility decline slows down as fertility level reduces. In fact this characteristic of the exponential function complies with the theory of fertility decline which asserts that when fertility attains lower levels, there will be no much room for further fertility decline.

As previously mentioned, the DHS-estimated fertility measures refer to the three-year period preceding the interviewing date, so if a time point is needed to refer fertility measures to, it must be the mid point of the three-year period. In order to calculate this point, 18 months was subtracted from the date of the mid data collection period of each survey. The date was then expressed as a calendar year and a fraction of the year, so that it can be used as the value of the independent variable in the model.

Initially, the four time points were used to fit above model using least square method, but the goodness of fit turns out to be weak ($R^2 = 0.48$). Hence, it has been decided to ignore the 2005 DHS survey, as its value of TFR (6.1) is evidently inconsistent with the declining trend, so this point may be viewed as an outlier to the general trend of TFR decline. When the model was fit using the data of the remaining three time points, the goodness of fit has substantially improved (R^2 approaches 1). The estimated model is:

$$\text{Ln}(TFR) = 16.282 - 0.00726 t$$

Thus, the estimated three time- point model was relied upon to estimate TFR in the years 2002, 2007, 2012, 2017, and 2022. [Note that $TFR = \text{Exp} \{ \text{Ln}(TFR) \}$]. Table 5 below shows the observed and estimated TFR for the period 1990-2022.

Table 5
TFR in the period 1990-2022

Year	Observed TFR	Estimated TFR
1990.205	6.2	--
1999.282	5.8	--
2002.5	--	5.7
2006.704	5.5	--
2007.5	--	5.5
2012.5	--	5.3
2017.5	--	5.1
2022.5	--	4.9

(The value of the year is shown as it is used in fitting the model and the estimation of TFR)

It is the estimated TFR which was used for population projection in the period 2002-2022. Since DEMPROM inputs require TFR values on annual basis, the intervening annual values were estimated by linear interpolation for each five-year projection period using TFR values of the two end points of the five-year period.

It is known that Total Fertility Rate measures the overall fertility level, whereas Age Specific Fertility Rates portray the age-pattern of fertility. The same value of TFR can result from different age-patterns of fertility. Nonetheless, generally there exists some sort of association between fertility level and its age pattern. With higher fertility levels the ASFR curve against age has a broader peak over a large part of the reproductive period and only drops down late in reproductive ages. While lower fertility is accompanied with an age pattern characterized by a narrow peak, which occurs relatively earlier in the reproductive span. For this reason, it is deemed important to project the future age pattern of fertility.

The same approach followed in estimating TFR in future years was exactly applied for the purpose of estimating the percentage of ASFR for each age group in the future, (the percentage of ASFR equals the ratio of ASFR of a certain age group to the summation of ASFR of all age groups, expressed as a percentage). A Log-linear model has been fit between the natural logarithm of the percentage of ASFR, in each age group, as dependent variable and time (year) as independent variable. The same three time points used in the case of TFR are used for ASFR model estimation. Table 6 shows the estimates of model parameters and the value of R square for each age group.

Table 6
Estimates of model parameters of $\ln(\text{percentage ASFR})$ versus year

Age Group	a'	b	R square
15-19	35.545	-0.0171	0.872
20-24	-3.674	0.003319	0.193
25-29	-2.041	0.002608	0.494
30-34	-0.203	0.001648	0.997
35-39	-8.321	0.005594	0.353
40-44	17.522	-0.0076	0.869
45-49	87.314	-0.0432	0.965

On the basis of above estimated models the age-pattern of fertility was estimated for the years 2002, 2007, 2012, 2017, and 2022. It is worth noting that when the summation of the estimated percentage of ASFR over the seven age groups deviates from 100, a prorating process has been done in order to get the summation exactly equal to 100. Table 7 exhibits the observed and estimated Percentage ASFR in the period 2002-2022.

Table 7
Observed and estimated percentage of ASFR in the
Period 2002-2022

Age group	1990.205	1999.282	2002.5	2006.70 4	2007.5	2012.5	2017.5	2022.5
15-19	4.8	4.5	3.7	3.6	3.4	3.1	2.8	2.6
20-24	18.2	20.6	19.6	19.1	19.9	20.2	20.4	20.6
25-29	23.6	23.3	24.2	24.7	24.4	24.7	24.9	25.1
30-34	21.7	22.0	22.2	22.3	22.4	22.5	22.5	22.6
35-39	17.2	16.3	17.9	19.0	18.4	18.8	19.3	19.7
40-44	10.8	10.5	10.1	9.5	9.7	9.3	8.9	8.5
45-49	3.7	2.8	2.3	1.8	1.8	1.4	1.2	0.9
Total	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0

(The value of the year is shown as it is used in fitting the model and the estimation of percentage ASFR, the first, second, and forth columns are observed)

The above estimates of percentages of ASFR were used for population projection in the period 2002-2022. Since DEMPROJ inputs require the percentages of ASFR on annual basis, the intervening annual values were estimated by linear interpolation for each five-year projection period using the percentages of ASFR of the two end points of the five-year period.

I.2.2.2 High Fertility Assumption

Under high fertility assumption, TFR estimate of the year 2007 remains constant till the end of the projection span. Similarly, ASFR is assumed to remain constant starting from 2007. Concerning the first five-year projection period (2002-2007), the estimated trends in TFR and percentage ASFR are applied as they represent real experience took place in this period.

I.2.2.3 Low Fertility Assumption

The developmental vision of Rwanda, known as 2020 Vision, states a set of fertility targets to be achieved over the years till 2020. The targeted TFR is 5.5, 4.1, and 3.9 for the years 2010, 2015 and 2020 respectively. The Vision 2020 targets are used as the lower fertility assumption as they appear to be too optimistic to realize in reality. Noticeably, the 2010 target (5.5) has already been achieved in 2007. Thus, only the remaining two fertility targets of 2015 and 2020 are taken into consideration in estimating future fertility. Linear interpolation is used to estimate annual TFR between 2007 and 2015, and between 2015 and 2020. TFR between 2020 and 2022 is extrapolated based on the linear trend in the period (2015-2020).

With the aim of maintaining consistency between TFR and ASFR, some appropriate estimates of percentages ASFR corresponding to fertility targets of

2015 and 2020 must be thought of. In this regard, we have estimated the time required to reach targeted TFR had the past trend in TFR continued in the future, (i.e. using the estimated log linear model of $\ln(\text{TFR})$ versus time used to estimate the median fertility variant). On the basis of such estimated time, the percentage of ASFR in the years 2015, 2020 and 2022 were estimated applying the estimated models of $\ln(\text{ASFR})$ versus time used in the case of median fertility assumption. The resulting estimates of percentages of ASFR corresponding to targeted TFR are shown in Table 8.

Table 8
Estimated percentages of ASFR and targeted
TFR for the years 2015, 2020, and 2022

Age group	2007	2015	2020	2022
15-19	3.4	1.6	1.4	1.3
20-24	19.9	21.5	21.7	21.7
25-29	24.4	25.6	25.7	25.8
30-34	22.4	22.5	22.5	22.4
35-39	18.4	21.8	22.3	22.5
40-44	9.7	6.7	6.2	6.1
45-49	1.8	0.3	0.2	0.2
TFR	5.5	4.1	3.9	3.82

TFR and percentages of ASFR for the projection intervening years are estimated by linear interpolation between each two adjacent points.

I.2.3 Mortality Projection

As indicated earlier, DHS is the only data source for fertility and mortality in Rwanda. DHS provides estimates for infant mortality, mortality rate for ages between 1 and 5 and Under 5 mortality rate. Mortality measures refer to the five years preceding the field visit. Nonetheless, when classified by several background variables, including child sex, mortality measures refer to the ten-year period preceding the field visit.

For the purpose of population projection, the survival function of appropriate model life tables that reflects current and assumed future mortality levels for each sex must be used. In the present situation, we ought to rely on either infant mortality rate or the mortality rate between ages 1 and 5, whichever more reliable, in order to select the appropriate model life table. Table 9 below shows infant mortality rate, mortality rate for ages between 1 and 5, and under 5 mortality rate for males and females based on the 2007/2008 Interim DHS survey.

Table 9
 Infant mortality rate, mortality rate for ages between 1 and 5,
 and under 5 mortality rate for males and females in
 the period (1997-2007)

Sex	Infant Mortality Rate	Mortality rate between ages 1-5	Under 5 mortality rate
Male	83	69	146
Female	71	55	123

Source: The 2007/2008 Interim DHS

Conventionally, when one mortality measure, of those shown in above table, is used to determine appropriate model life table, it is supposed to be the observed Infant Mortality Rate as it has the highest influence on life expectancy at birth. The observed value of mortality rate between ages 1 and 5, is only used to determine the appropriate family (region) of model life table. In other words, the family (region) which gives the closest value (to the observed one) of the mortality rate between ages 1 and 5 would be identified as the applicable family (region) of the model life table.

Above strategy of identifying model life table was attempted, but unfortunately the model value of the mortality rate between ages 1 and 5 was much lower than the observed value shown in the table above. The same observation has been noted in all the four families of Coale and demeny Model Life Tables, and the five regions of the U.N. Model Life Tables. This situation gives rise to an important question, is DHS infant mortality rate underestimate? In fact it is likely so. One other evidence that lends support to this finding is the recently measured conventional infant mortality rate for the Western Province which reaches about 100 per 1000 live births.

In view of the above, it becomes evident that the DHS mortality rate between ages 1 and 5 is likely to be more reliable than infant mortality rate as the latter is subjected to more underreporting especially for infant deaths who died immediately after birth: some respondents may have failed to report them. For this reason, it has been relied upon the DHS mortality rate between ages 1 and 5 to select the appropriate model life table, for which the selected family (region) is the nearest one to the observed DHS infant mortality rate. It has been found that Coale and Demeny Model Life Table (North Family) is the most appropriate one. Surprisingly, the U.N Population Projection has also selected the same model life table for Rwanda (World Population Prospect, the sixth Revision). According to Coale and Demeny Model Life Table (North Family), and the values of mortality rate between ages 1 and 5 for males and females shown in Table 9, life expectancy at birth is 46.7 for males and 49.8 for females. Noteworthy is that the mortality rate between ages 1 and 5 and consequently life expectancy at birth refer to the year 2002, as being the mid point of the ten-year period of measuring infant and early childhood mortality by sex.

The U.N. approach of projecting future mortality level has been followed. The rationale of this approach is that the pace of mortality decline slows down with the attainment of lower mortality levels with slight difference between males and

females. Table 10 exhibits the projected values of life expectancy at birth for the period 2002-2022.

Table 10
Projected Life Expectancy at birth
In the period (2002-2022)

Year	Male	Female
2002	46.7	49.8
2007	48.6	52.3
2012	50.8	54.8
2017	52.8	56.8
2022	54.8	58.7

As DEMPROJ inputs require the values of life expectancy at birth on annual basis, the intervening annual values were estimated by linear interpolation for each five-year projection period using the values of life expectancy at birth of the two end points of the five-year period.

I.2.4 Migration Projection

Before mid Nineties Rwanda experienced massive outflow migratory movements until the civil war and genocide was over. After mid Nineties, however, and with the restoration of peace and order, return migration has started in low numbers in the beginning and increased numbers in subsequent years. Since the beginning of 2000, and due to further political and economic stability that Rwanda has witnessed, international migration to and from Rwanda has become of lower magnitude to the extent that it may have no tangible effects on the population size and structures. For this reason, it may be plausible to assume that net migration is null during the projection span.

I.2.5 Sex Ratio at Birth

Defined as the number of male births per 100 female births, recent evidences, the 2008 Base-line Survey, has shown that sex ratio at birth in Rwanda is about 104%. This value of sex ratio at birth was kept constant throughout the projection years.

CHAPTER II: SUMMARY RESULTS

II.1 FERTILITY

I.1.1 Medium

year	Input TFR	GRR	NRR	Mean Age of Child bearing	Child-woman ratio
